GENERAL INSTRUCTIONS

IMPORTANT NOTICE

All maintenance and repair operations described in this manual should be carried out exclusively by the authorized workshops. All instructions detailed should be carefully observed and special equipment indicated should be used if necessary.

Everyone who carries out service operations described without carefully observing these prescriptions will be directly responsible of deriving damages.

SHIMMING

At each adjustment, select adjusting shims, measure them individually using a micrometer and then sum up recorded values. Do not rely on measuring the whole shimming set, which may be incorrect, or on the rated value indicated for each shim.

ROTATING SHAFT SEALS

To correctly install rotating shaft seals, observe the following instructions:

- Let the seal soak into the same oil as it will seal for at least half an hour before mounting;
- Thoroughly clean the shaft and ensure that the shaft working surface is not damaged;
- Place the sealing lip towards the fluid. In case of a hydrodynamic lip, consider the shaft rotation direction and orient grooves in order that they deviate the fluid towards the inner side of the seal;
- Coat the sealing lip with a thin layer of lubricant (oil rather than grease) and fill the gap between the sealing lip and the dust lip of double lip seals with grease;
- Insert the seal into its seat and press it down using a flat punch. Do not tap the seal with a hammer or a drift;

- Take care to insert the seal perpendicularly to its seat while you are pressing it. Once the seal is settled, ensure that it contacts the thrust element, if required;
- To prevent damaging the sealing lip against the shaft, place a suitable protection during installation.

O RINGS

Lubricate the O rings before inserting them into their seats. This will prevent the O rings from roll over and twisting during mounting, which will jeopardize sealing.

SEALERS

Apply silicone/gasket eliminator over the mating surfaces marked with an X in the figures. Before applying the sealer, prepare the surface as follows:

- remove possible scales using a metal brush;
- thoroughly degrease the surfaces using one of the following cleaning agents: trichlorethylene, diesel fuel or a water and soda solution.

BEARINGS

It is advisable to heat the bearings to 80° to 90°C (176° to 194°F) before mounting them on their shafts and cool them down before inserting them into their seats with external tapping.

SPRING PINS

When mounting split socket spring pins, ensure that the pin notch is oriented in the direction of the effort to stress the pin.

Spiral spring pins should not be oriented during installation.

GENERAL INSTRUCTIONS

PRECAUTIONARY NOTICE

OVERHAUL

Op. 10 001 10

ENGINE

Removal

————  **DANGER**  ————

Lift and handle all heavy parts using suitable lifting equipment.

Make sure that assemblies or parts are supported by means of suitable slings and hooks. Make sure that no-one is standing in the vicinity of the load to be lifted.

————  **WARNING**  ————

Always use appropriate tools to align fixing holes. NEVER USE YOUR FINGERS OR HANDS.

Proceed as follows.

1. Carry out operation **18 110 10** Clutch Removal (see sect. 18).
2. Remove the clogged air filter sensor connection (1).
3. Disconnect the horn connection (1).

4

5

4. Loosen the clamps (1, 2 and 3) and remove the inlet manifold.

6

5. Unscrew the band clamps and detach the upper (2) and lower radiator hoses, detach the radiator bracket (1).

6. Position two fixed stands under the front axle support and under the engine. Attach the chains so that the engine is balanced during hoisting and position two wood blocks between the support and the front axle, to prevent oscillation.
7. Loosen the front axle support retaining bolts (1).
8. Remove the engine from the axle-support unit.

Installation

⚠ WARNING ⚠
Always use appropriate tools to align fixing holes. NEVER USE YOUR FINGERS OR HANDS.

Apply the prescribed tightening torques - see the "Contents".

1. Install the front axle-support unit on the engine.
2. Connect and secure the upper and lower radiator hoses and the connecting bracket.
3. Install the inlet manifold.
4. Connect the horn and clogged air filter connections.
5. Carry out operation **18 110 10** Clutch Installation (see Section 18).

Op. 10 001 30**Compression Test**

In case of poor engine performance, in addition to checking the fuel injection system (injection nozzles and injection pump), also test the compression on each cylinder.

Do not use matches, lighters, blow torches or any form of naked flame as a source of light when inspecting the engine due to the presence of inflammable fluids and vapor.

Compression Ratio

The compression ratio is a measure of the quantity of air drawn into the cylinder, and provides an indication of the efficiency of the sealing elements in the cylinder (piston rings and valves).

Uniform compression in all the cylinders ensures that they all perform an equal amount of work, provided that each cylinder is injected with the same quantity of fuel at the right time.

Low compression not only reduces engine performance, it also causes incomplete fuel combustion due to the lack of available combustion air.

The engine therefore gives poor performance with excessive fuel consumption and, consequently, exhaust smoke and restriction of the exhaust passages.

As the compression ratio also varies with the temperature of the engine (cold engines produce lower compression values than hot engines), the compression should only be tested when the engine is at normal operating temperature.

Compression should be tested using the compression test kit **380000303**, as follows:

- 1) Run the engine until it reaches normal operating temperature.
- 2) Switch off the engine.
- 3) Disconnect the lead from the engine stop electromagnet on the injection pump in order to close the valve and block the flow of fuel to the injectors.
- 4) Remove the injector from the cylinder to be tested.
- 5) Turn the engine over a few times with the starter motor in order to expel any carbon residue.

6) Fit the dummy injector tool **380000617** in place of the injector removed previously, interposing the copper sealing washer.

7) Connect the compression test instrument **380000303** and take readings while turning the engine over with the starter motor.

On engines in perfect working order, with the sump oil at approx. 40 °C (104 °F) at sea level (760 mm - 29.92 in. - of mercury) and at an engine speed of 200 to rpm, the compression should be 25 to 27 bar (369 to 398 psi).

8) Test the compression on the other cylinders, repeating steps 4-5-6-7, bearing in mind that:

The minimum permissible compression on a used engine is 21.6 bar (313 psi).

The maximum permissible compression difference between cylinders is 3 bar (43 psi).

Every 100 meters (109.36 yards) above sea level corresponds to a reduction in compression by approx. 1%.

Uniform Compression

Although high compression is important, it is more important for smooth engine running that compression is uniform in all cylinders.

Low compression readings

If extremely low pressure readings are obtained on one cylinder it is advisable to repeat the test.

Before testing this time, pour approx. one spoonful of engine oil into the cylinder through the injector bore.

Turn over the engine a few times to distribute the oil evenly over the cylinder walls, and then repeat the test.

If the second test readings are significantly higher, the problem may be worn piston rings, out-of-round or damaged pistons or cylinders.

If the second test readings are not higher, the problem will be the valves.

On the other hand, if the second test reading shows only a slight improvement, the problem will be due to both the valves and the rings.
